

It's sink or swim for coastal towns

Experts say government must plan now to manage effects of rising sea levels in North Carolina

By Bruce Henderson, The Charlotte Observer

The sea that sculpted North Carolina's coast, from its arc of barrier islands to the vast, nurturing sounds, is reshaping it once again.

Water is rising three times faster on the North Carolina coast than it did a century ago as warming oceans expand and land ice melts, recent research has found. It's the beginning of what a North Carolina science panel expects will be a one metre increase by 2100.

Rising sea level is the clearest signal of climate change in North Carolina. Few places in the United States stand to be more transformed.

About 5,000 square km of its low, flat coast is one metre or less above water. At risk are more than 30,500 homes and other buildings, including some of the state's most expensive real estate.

Economists say \$6.9 billion in property, in just the four counties they studied, will be at risk from rising seas by late this century.

BILLIONS IN LOSSES

Climate models predict intensifying storms that could add billions of dollars more in losses to tourism, farming and other businesses.

While polls show growing public skepticism of global warming, the people paid to worry about the future -engineers, planners, insurance companies -are already bracing for a wetter world.

"Sea-level rise is happening now. This is not a projection of something that will happen in the future if climate continues to change," said geologist Rob Young of Western Carolina University, who studies developed shorelines.

Nobody knows how high or fast the sea will rise. Water isn't likely to submerge all the state's low coastland because landowners will fight back.

But the coast visitors know, with its fringe of salt marshes, its fluffy beaches and old harbour towns, might look like a different place a few generations from now.

That won't be the work of rising water alone, but of quirks in North Carolina's coastal topography. The flat ground means even a small increase in water level will spread far inland. The coastal plain is also sinking, the geological legacy of the last ice age. The Outer Banks, some scientists predict, could disintegrate into a string of high spots reachable only by boat.

If storms punch new inlets through the islands, the brackish sounds and wetlands that serve as vital nurseries for Atlantic coast seafood species would turn into open saltwater. Predatory fish would pour into previously protected waters. Marshes would migrate inland or drown.

SANCTUARY THREATENED

Dead bald cypress trees already rim the Albemarle-Pamlico Peninsula, greying in the encroaching salty water that engulfed and killed them.

Much of the peninsula, which juts toward the northern Banks and is one the state's richest wildlife sanctuaries, could be underwater by century's end.

Human habitats will be forced into momentous decisions: fortify or flee. A row of beach houses in the old resort town of Nags Head is collapsing into the surf now as the town plans a \$36-million project to pump fresh sand onto its eroding strand this spring.

Down the coast, in North Topsail Beach, property owners are waffling on helping to pay for a \$10-million nourishment project.

As sand moves around, some beaches such as Sunset widen.

But communities that control about one-third of the state's 535 km of beach face similar sink-or-swim decisions.

The average cost of pumping sand onto eroding beaches is \$600,000 a kilometre repeated about every five years as storms wash it away.

One coastal village repeatedly swamped by storms is barricading itself, Dutch-style, behind a 27-km dike. State planners are preparing detailed maps of future high-water lines, groundwork for an eventual retreat inland of both people and buildings.

"To me, it's the big planning problem for this century," said Scott Shuford, planning director in Onslow County, on the southern coast.

"There's an element of urgency about it, but at the same time a recognition that it can't be solved easily."

It seems implausible that an almost imperceptible rise in the sea -about the thickness of two nickels a year -could cause such havoc.

It took only an 20 cm global rise to threaten the iconic Cape Hatteras Lighthouse, which was 500 metres from the Atlantic when it was built in 1870.

By 1999, when hydraulic jacks gingerly nudged the striped brick tower inland, waves crashed at its foundation.

SHAPING THE COAST

Long before people were capable of such engineering, the sea and wind were shaping the Carolina coast.

After the last ice age peaked 11,000 years ago, melting glaciers turned Pamlico Creek into Pamlico Bay, then into Pamlico Sound.

Coastal geologists who reconstructed sea-level changes on the northeastern North Carolina coast say levels were stable for 3,000 years.

The sea began rising in the 19th century.

The rate of climb doubled again in the 20th century, with a further quickening in the past 30 years.

Alonzo Leary gauges the changes over the 74-year span of his life. Raised near Albemarle Sound in a farming community called Alligator, he left as a young man to find work.

He returned 20 years later to find old swimming holes flooded and the sound closer to road level.

"I notice that the swamps stay full of water most of the time," Leary said.

Scientists envision more acceleration this century. Some say seas could rise to as much as two metres above current levels by 2100 if large ice masses melt in Greenland and Antarctica.

To help plan for building new roads, bridges and other infrastructure, a state panel of engineers and scientists estimated last year that the sea will rise 25 cm to 1.4 metres by 2100, with one metre the midpoint.

When state transportation engineer Ted Devens and his colleagues recently designed a widening a 45-km stretch of U.S. 64, they raised the roadbed by 30 cm to allow for rising seas. It was a first for a North Carolina Department of Transportation road project.

"What we're trying to do is get away from the hype and just look at the data," said Devens, who works in project development and environmental analysis.

"Our data tells us sea level is rising. . What do you plan for? That's been the big question."

Other key questions: where to move both structures and people, and how to pay for it?

In the little town of Plymouth, storms regularly submerge the century-old sewage system.

It will only get worse as water in the sound rises.

Rob Young, the coastal geologist, said if the state were serious about adapting to rising seas, it would be smarter in responding to the storms that already hammer the coast.

Beach communities shredded by hurricanes are typically built back, sometimes repeatedly.

Taxpayers subsidize federal flood insurance, roads and bridges.

If seas rise by one metre, Young said, engineer s could fix the holes storms would blow through the rim of barrier islands, as long as the state can afford repairs.

The problem of the future is that Charleston, Miami and other East coast cities also would be struggling to keep their heads above water.

"If we have to fix Manhattan," he said, "Hatteras is not going to compete for money real well."
